## 3) (10 pts) DSN (Backtracking)

A D-digit divisible number is a positive integer of D digits (with no leading digits zero) such that each of its prefixes of k digits is a number divisible by k. For example, 52240 is a 5-digit divisible number because 5 is divisible by 1, 52 is divisible by 2, 522 is divisible by 3, 5224 is divisible by 4 and 52240 is divisible by 5. Assume that there exists a function as specified below:

```
int kDigitPrefixValue(char* number, int k);
```

such that if number is storing the string version of an integer that is at least k digits long, then the function will return the integer value of the first k digits represented in number. For example, kDigitPrefixValue("52240", 4) will return the integer 5224.

Complete the recursive function below so that it will print out all 6-digit divisible numbers. (A complete wrapper function is provided for you, so just fill out the blanks in the recursive function.)

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
int kDigitPrefixValue(char* number, int k);
void printkDivisibleRec(char* number, int k);
void wrapper(int numdigits);
int main() {
  wrapper(6);
   return 0;
void wrapper(int numdigits) {
   char* tmp = malloc(sizeof(char)*(numdigits+1));
   int i;
   for (i=0; i \le numdigits; i++) tmp[i] = '0';
   tmp[numdigits] = '\0';
   printkDivisibleRec(tmp, 0);
   free(tmp);
void printkDivisibleRec(char* number, int k) {
   if (k == strlen(number)) {
       printf("%s\n", number);
       return;
   int i = k == 0 ? 1 : 0;
   for (; i < ; i++) {
       number[ ___ ] = (char)( ___ +'0');
                                    (number, _____);
       int prefix =
       if ( _____ %( ____ ) == ___ )
                         (number, );
   }
}
```
